Topics in This Section

• **Motivation**
  – And comparing concurrent and parallel programming

• **Basic approach**
  – Make a task list with Executors.newFixedThreadPool
  – Add tasks to list with taskList.execute(someRunnable)

• **Variations on the theme**
  – Separate classes that implement Runnable
  – Main app implements Runnable
  – Inner classes that implement Runnable
  – Lambda expressions

• **Related topics**
  – Race conditions and synchronization
  – Helpful Thread-related methods
  – Advanced topics in concurrency

Overview
Motivation for Concurrent Programming

- **Pros**
  - Advantages even on single-processor systems
    - Efficiency
      - Downloading network data files
    - Convenience
      - A clock icon
    - Multi-client applications
      - HTTP Server, SMTP Server
  - Many computers have multiple processors
    - Find out via Runtime.getRuntime().availableProcessors()
- **Cons**
  - Significantly harder to debug and maintain than single-threaded apps

Concurrent vs. Parallel Programming

- **Concurrent**
  - Tasks that overlap in time.
    - The system might run them in parallel on multiple processors, or might switch back and forth among them on the same processor.
- **Parallel**
  - Tasks that run at the same time on different processors.
Java Threads (Concurrent) vs Fork/Join Framework (Parallel)

• **Using threads**
  – When task is relatively large and self-contained
  – Usually when you are waiting for something, so would benefit even if there is only one processor
  – Covered in this lecture
• **Using fork/join**
  – When task starts large but can be broken up repeatedly into smaller pieces, then combined for final result.
  – No benefit if there is only one processor
  – Covered in next lecture
    • Also, parallel version of Streams, covered in separate lectures, uses fork/join framework under the hood

Basic Steps for Concurrent Programming

Customized Java EE Training: http://courses.coreservlets.com/

Steps for Concurrent Programming

• Make a task list

```java
ExecutorService taskList = Executors.newFixedThreadPool(poolSize);
• The poolSize is the maximum number of simultaneous threads. For many apps, it is higher than the number of tasks, so each task has a separate thread.
• There are other types of thread pools, but a fixed thread pool is simplest and most common

• Add Runnable tasks to the list

```java
taskList.execute(someRunnable);
```

Variations for Adding Runnable to Task List

• Make separate class that implements Runnable

```java
taskList.execute(new MySeparateRunnableClass(…));
```

• Have your existing class implement Runnable.

```java
taskList.execute(this);
```

• Use an inner class.

```java
taskList.execute(new MyInnerRunnableClass(…));
```

• Use a lambda

```java
taskList.execute(() -> codeForRunMethod());
```
Approach One: Separate Classes that Implement Runnable

Thread Mechanism One: Separate Runnable Class

- Make class that implements Runnable
  - No import statements needed: Runnable is in java.lang
- Put actions to be performed in run method
  ```java
  public class MyRunnable implements Runnable {
      public void run() { someBackgroundTask(); }
  }
  ```
- Create instance of your class
  - Or lots of instances, if you want lots of threads
- Pass instance to ExecutorService.execute
  ```java
  taskList.execute(new MyRunnable(...));
  ```
  - The number of simultaneous threads won’t exceed the maximum size of the pool
Separate Runnable Class: Template Code

```java
public class MainClass extends SomeClass {
    ...
    public void startThreads() {
        int poolSize = ...;
        ExecutorService taskList = Executors.newFixedThreadPool(poolSize);
        for(int i=0; i<something; i++) {
            taskList.execute(new SomeTask(...));
        }
    }
}

public class SomeTask implements Runnable {
    public void run() {
        // Code to run in the background
    }
}
```

Thread Mechanism One: Example

```java
public class Counter implements Runnable {
    private final App1 mainApp;
    private final int loopLimit;

    public Counter(App1 mainApp, int loopLimit) {
        this.mainApp = mainApp;
        this.loopLimit = loopLimit;
    }

    public void run() {
        for(int i=0; i<loopLimit; i++) {
            String threadName = Thread.currentThread().getName();
            System.out.printf("%s: %s%n", threadName, i);
            mainApp.pause(Math.random());
        }
    }
}
```
import java.util.concurrent.*;

public class App1 extends SomeClass {
    public App1() {
        ExecutorService taskList = Executors.newFixedThreadPool(100);
        taskList.execute(new Counter(this, 6));
        taskList.execute(new Counter(this, 5));
        taskList.execute(new Counter(this, 4));
        taskList.shutdown();
    }

    public void pause(double seconds) {
        try {
            Thread.sleep(Math.round(1000.0 * seconds));
        } catch (InterruptedException ie) { }
    }
}

public class App1Test {
    public static void main(String[] args) {
        new App1();
    }
}
Thread Mechanism One: Results

pool-1-thread-1: 0
pool-1-thread-2: 0
pool-1-thread-3: 0
pool-1-thread-2: 1
pool-1-thread-2: 2
pool-1-thread-1: 1
pool-1-thread-3: 1
pool-1-thread-2: 3
pool-1-thread-3: 2
pool-1-thread-1: 2
pool-1-thread-1: 3
pool-1-thread-1: 4
pool-1-thread-3: 3
pool-1-thread-2: 4
pool-1-thread-1: 5

Pros and Cons of Separate-Class Approach

• Advantages
  – Loose coupling
    • Can change pieces independently
    • Can reuse Runnable class in more than one application
  – Passing arguments
    • If you want different threads to do different things, you pass args to constructor, which stores them in instance variables that run method uses
  – Little danger of race conditions
    • You usually use this approach when there is no data shared among threads, so no need to synchronize.

• Disadvantages
  – Hard to access main app
    • If you want to call methods in main app, you must
      – Pass reference to main app to constructor, which stores it
      – Make methods in main app be public
Approach Two: Main App Implements Runnable

Thread Mechanism Two: Main App Implements Runnable

- **Have main class implement Runnable**
  - Put actions in run method of existing class
    ```java
    public class MyClass extends Something implements Runnable {
        ...
        public void run() {
            ...
        }
    }
    ```

- **Pass the instance of main class to execute**
  ```java
  taskList.execute(this);
  ```
Main App Implements Runnable: Main Differences vs. Sep. Class

• **Good news**
  – run can easily call methods in main class, since it is *in* that class

• **Bad news**
  – If run accesses any shared data (instance variables), you have to worry about conflicts (race conditions)
  – No constructor, so very hard to pass arguments, and thus each task starts off the same way

---

### Template Code

```java
public class ThreadedClass extends AnyClass implements Runnable {

    public void run() {
        // Code to run in background
    }

    public void startThreads() {
        int poolSize = ...;
        ExecutorService taskList = Executors.newFixedThreadPool(poolSize);
        for(int i=0; i<someSize; i++) {
            taskList.execute(this);
        }
    }

    ...
}
```
Thread Mechanism Two: Example

```java
public class App2 extends SomeClass implements Runnable {
    private final int loopLimit;

    public App2(int loopLimit) {
        this.loopLimit = loopLimit;
        ExecutorService taskList =
            Executors.newFixedThreadPool(100);
        taskList.execute(this);
        taskList.execute(this);
        taskList.execute(this);
        taskList.shutdown();
    }

    private void pause(double seconds) {
        try {
            Thread.sleep(Math.round(1000.0 * seconds));
        } catch (InterruptedException ie) { }
    }
}
```

Class continued on next slide

Thread Mechanism Two: Example (Continued)

```java
public void run() {
    for(int i=0; i<loopLimit; i++) {
        String threadName =
            Thread.currentThread().getName();
        System.out.printf("%s: %s%n", threadName, i);
        pause(Math.random());
    }
}
```

Class continued on next slide
Thread Mechanism Two: Example (Continued)

```java
public class App2Test {
    public static void main(String[] args) {
        new App2(5);
    }
}
```

Thread Mechanism Two: Results

```
pool-1-thread-3: 0
pool-1-thread-1: 0
pool-1-thread-2: 0
pool-1-thread-2: 1
pool-1-thread-3: 1
pool-1-thread-3: 2
pool-1-thread-1: 1
pool-1-thread-2: 2
pool-1-thread-3: 3
pool-1-thread-2: 3
pool-1-thread-1: 2
pool-1-thread-3: 4
pool-1-thread-1: 3
pool-1-thread-2: 4
pool-1-thread-1: 4
```
Pros and Cons of Approach

• **Advantages**
  - Easy to access main app.
    • run is already inside main app. Can access any public or private methods or instance variables.

• **Disadvantages**
  - Tight coupling
    • run method tied closely to this application
  - Cannot pass arguments to run
    • So, you either start a single thread only (quite common), or all the threads do very similar tasks
  - Danger of race conditions
    • You usually use this approach specifically because you want to access data in main application. So, if run modifies some shared data, you must synchronize.
Thread Mechanism Three: Runnable Inner Class

- **Have inner class implement Runnable**
  - Put actions in run method of inner class
    ```java
    public class MyClass extends Whatever {
        ...
        private class InnerClass implements Runnable {
            public void run() {
                ...
            }
        }
    }
    ```

- **Pass instances of inner class to execute**
  ```java
  taskList.execute(new InnerClass(...));
  ```

Inner Class Implements Runnable: Template Code

```java
public class MainClass extends AnyClass {
    public void startThreads() {
        int poolSize = ...;
        ExecutorService taskList = Executors.newFixedThreadPool(poolSize);
        for(int i=0; i<someSize; i++) {
            taskList.execute(new RunnableClass(...));
        }
    }
    ...

    private class RunnableClass implements Runnable {
        public void run() {
            // Code to run in background
        }
    }
}
```
Minor Variation: Anonymous Inner Class

public class MainClass extends AnyClass {
    public void startThreads() {
        int poolSize = ...;
        ExecutorService taskList = Executors.newFixedThreadPool(poolSize);
        for(int i=0; i<someSize; i++) {
            taskList.execute(new Runnable() {
                public void run() {
                    ...
                }
            });
        }
    }
}

Thread Mechanism Three: Example

public class App3 extends SomeClass {
    public App3() {
        ExecutorService taskList = Executors.newFixedThreadPool(100);
        taskList.execute(new Counter(6));
        taskList.execute(new Counter(5));
        taskList.execute(new Counter(4));
        taskList.shutdown();
    }

    private void pause(double seconds) {
        try {
            Thread.sleep(Math.round(1000.0 * seconds));
        } catch (InterruptedException ie) { }
    }
}
Thread Mechanism Three: Example (Continued)

private class Counter implements Runnable {
    // Inner class
    private final int loopLimit;

    public Counter(int loopLimit) {
        this.loopLimit = loopLimit;
    }

    public void run() {
        for (int i=0; i<loopLimit; i++) {
            String threadName = Thread.currentThread().getName();
            System.out.printf("%s: %s%n", threadName, i);
            pause(Math.random());
        }
    }
}

You can also use anonymous inner classes. This is not different enough to warrant a separate example here, especially since we showed examples in the section on event handling.

Thread Mechanism Three: Example (Continued)

public class App3Test {
    public static void main(String[] args) {
        new App3();
    }
}
Thread Mechanism Three: Results

pool-1-thread-2: 0
pool-1-thread-1: 0
pool-1-thread-3: 0
pool-1-thread-3: 1
pool-1-thread-1: 1
pool-1-thread-1: 2
pool-1-thread-2: 1
pool-1-thread-3: 2
pool-1-thread-3: 3
pool-1-thread-1: 3
pool-1-thread-1: 4
pool-1-thread-1: 5
pool-1-thread-2: 2
pool-1-thread-2: 3
pool-1-thread-2: 4

Pros and Cons of Approach

• Advantages

    • Methods in inner classes can access any public or private methods or instance variables of outer class
  – Can pass arguments to run
    • As with separate classes, you pass args to constructor, which stores them in instance variables that run uses

• Disadvantages
  – Tight coupling
    • run method tied closely to this application
  – Danger of race conditions

Four: Lambda Expressions

Customized Java EE Training: http://courses.coreservlets.com/
Java 7, Java 8, JSF 2, PrimeFaces, Android, JSP, Ajax, jQuery, Spring MVC, RESTful Web Services, GWT, Hadoop
Developed and taught by well-known author and developer. At public venues or onsite at your location.

Preview of Lambdas

- **Anonymous inner class**

  ```java
  taskList.execute(new Runnable() {
      @Override
      public void run() {
          doSomeTask(...);
      }
  });
  ```

- **Lambda equivalent**

  ```java
  taskList.execute(() -> doSomeTask(...));
  ```

Lambda expressions are covered in later tutorial section.

Summary of Approaches

Pros and Cons

• **Separate class that implements Runnable**
  − Cannot easily access data in main class (and only public data)
  − Can pass args to run (indirectly via constructor and instance variables)
  − Usually no worry about race conditions

• **Main class implements Runnable**
  − Can easily access data in main class
  − Cannot pass args to run
  − Must worry about race conditions

• **Inner class implements Runnable**
  − Can easily access data in main class
  − Can pass args to run (indirectly via constructor and instance variables)
  − Must worry about race conditions

• **Lambdas**
  − Can easily access data in main class
  − Cannot pass args to run (no instance variables)
  − Must worry about race conditions
Example: Template for a Multithreaded Network Server

```java
import java.net.*;
import java.util.concurrent.*;
import java.io.*;

public class MultithreadedServer {
    private int port;

    public MultithreadedServer(int port) {
        this.port = port;
    }

    public int getPort() {
        return(port);
    }

    public void listen() {
        int poolSize =
           100 * Runtime.getRuntime().availableProcessors();
        ExecutorService taskList =
            Executors.newFixedThreadPool(poolSize);
        try {
            ServerSocket listener = new ServerSocket(port);
            Socket socket;
            while(true) { // Run until killed
                socket = listener.accept();
                taskList.execute(new ConnectionHandler(socket));
            }
        } catch (IOException ioe) {
            System.err.println("IOException: " + ioe);
            ioe.printStackTrace();
        }
    }
}
```

MultithreadedServer.java (Continued)

The later sections on network programming will give details on ServerSocket and Socket. But the basic idea is that the server accepts a connection and then puts it in the queue of tasks so that it can be handled in a background thread. The network servers section will give a specific example of this code applied to making an HTTP server.
public class ConnectionHandler implements Runnable {
    private Socket socket;

    public ConnectionHandler(Socket socket) {
        this.socket = socket;
    }

    public void run() {
        try {
            handleConnection(socket);
        } catch (IOException ioe) {
            System.err.println("IOException: " + ioe);
            ioe.printStackTrace();
        }
    }

    public void handleConnection(Socket socket)
        throws IOException{
        // Do something with socket
    }
}
Race Conditions: Example

```java
public class RaceConditionsApp implements Runnable {
    private final static int LOOP_LIMIT = 5;
    private final static int POOL_SIZE = 10;
    private int latestThreadNum = 0;

    public RaceConditionsApp() {
        ExecutorService taskList;
        taskList = Executors.newFixedThreadPool(POOL_SIZE);
        for (int i=0; i<POOL_SIZE; i++) {
            taskList.execute(this);
        }
    }
}
```

Race Conditions: Example (Continued)

```java
public void run() {
    int currentThreadNum = latestThreadNum;
    System.out.println("Set currentThreadNum to "+currentThreadNum);
    latestThreadNum = latestThreadNum + 1;
    for (int i=0; i<LOOP_LIMIT; i++) {
        doSomethingWith(currentThreadNum);
    }
}

private void doSomethingWith(int threadNumber) {
    // Blah blah
}
```

• What’s wrong with this code?
Race Conditions: Result

- **Expected Output**
  - Set currentThreadNum to 0
  - Set currentThreadNum to 1
  - Set currentThreadNum to 2
  - Set currentThreadNum to 3
  - Set currentThreadNum to 4
  - Set currentThreadNum to 5
  - Set currentThreadNum to 6
  - Set currentThreadNum to 7
  - Set currentThreadNum to 8
  - Set currentThreadNum to 9

- **Occasional Output**
  - Set currentThreadNum to 0
  - Set currentThreadNum to 1
  - Set currentThreadNum to 2
  - Set currentThreadNum to 3
  - Set currentThreadNum to 4
  - Set currentThreadNum to 5
  - Set currentThreadNum to 5
  - Set currentThreadNum to 7
  - Set currentThreadNum to 8
  - Set currentThreadNum to 9

In older Java versions, the error showed up rarely: only about 1 in 50 times. In newer Java versions (that give each thread a smaller time slice and where the underlying computer is faster), it happens often. There is another version of the code in the Eclipse project that even on new Java versions, manifests the problem only about 1 in 50 times.

Race Conditions: Solution?

- **Do things in a single step**

```java
public void run() {
    int currentThreadNum = latestThreadNum++;
    System.out.println("Set currentThreadNum to " + currentThreadNum);
    for (int i=0; i<LOOP_LIMIT; i++) {
        doSomethingWith(currentThreadNum);
    }
}
```

This “solution” does not fix the problem. In some ways, it makes it worse!
**Arbitrating Contention for Shared Resources**

- **Synchronizing a section of code**
  ```java
  synchronized(someObject) {
    code
  }
  ```

- **Normal interpretation**
  - Once a thread enters that section of code, no other thread can enter until the first thread exits.

- **Stronger interpretation**
  - Once a thread enters that section of code, no other thread can enter any section of code that is synchronized using the same “lock” object
  - If two pieces of code say “synchronized(blah)”, the question is if the blah’s are the same object instance.

- **Synchronizing an entire method**
  ```java
  public synchronized void someMethod() {
    body
  }
  ```

- **Note that this is equivalent to**
  ```java
  public void someMethod() {
    synchronized(this) {
      body
    }
  }
  ```
public void run() {
    int currentThreadNum;
    synchronized(this) {
        currentThreadNum = latestThreadNum;
        System.out.println("Set currentThreadNum to " + currentThreadNum);
        latestThreadNum = latestThreadNum + 1;
    }
    for (int i=0; i<LOOP_LIMIT; i++) {
        doSomethingWith(currentThreadNum);
    }
}
### Methods in Thread Class

- **Thread.currentThread()**
  - Gives instance of Thread running current code

- **Thread.sleep(milliseconds)**
  - Puts calling code to sleep. Useful for non-busy waiting in all kinds of code, not just multithreaded code. You must catch InterruptedException, but you can ignore it:
    - try { Thread.sleep(someMilliseconds); } catch (InterruptedException ie) { }
  - See also TimeUnit.SECONDS.sleep, TimeUnit.MINUTES.sleep, etc.
    - Same idea except takes sleep time in different units.

- **someThread.getName(), someThread.getId()**
  - Useful for printing/debugging, to tell threads apart

### Methods in ExecutorService Class

- **execute(Runnable)**
  - Adds Runnable to the queue of tasks

- **shutdown**
  - Prevents any more tasks from being added with execute (or submit), but lets current tasks finish

- **shutdownNow**
  - Attempts to halt current tasks. But author of tasks must have them respond to interrupts (i.e., catch InterruptedException), or this is no different from shutdown.

- **awaitTermination**
  - Blocks until all tasks are complete. Must shutdown() first.
Lower-Level Threading

- **Use Thread.start(someRunnable)**
  - Implement Runnable, pass to Thread constructor, call start
    - `Thread t = new Thread(someRunnable);`
    - `t.start();`
  - About same effect as taskList.execute(someRunnable), except that you cannot put bound on number of simultaneous threads.
  - Mostly a carryover from pre-Java-5 days; still widely used.

- **Extend Thread**
  - Put run method in Thread subclass, instantiate, call start
    - `SomeThread t = new SomeThread(...);`
    - `t.start();`
  - A holdover from pre-Java-5; has little use in modern Java applications.

Advanced Topics
Callable

• **Runnable**
  – “run” method runs in background. No return values, but run can do side effects.
  – Use “execute” to put in task queue

• **Callable**
  – “call” method runs in background. It returns a value that can be retrieved after termination with “get”.
  – Use “submit” to put in task queue.
  – Use invokeAny and invokeAll to block until value or values are available
    • Example: you have a list of links from a Web page and want to check status (404 vs. good). Submit them to a task queue to run concurrently, then invokeAll will let you see return values when all links are done being checked.

Types of Task Queues

• **Executors.newFixedThreadPool(nThreads)**
  – Simplest and most widely used type. Makes a list of tasks to be run in the background, but with caveat that there are never more than nThreads simultaneous threads running.

• **Executors.newScheduledThreadPool**
  – Lets you define tasks that run after a delay, or that run periodically. Replacement for pre-Java-5 Timer class.

• **Executors.newCachedThreadPool**
  – Optimized version for apps that start many short-running threads. Reuses thread instances.

• **Executors.newSingleThreadExecutor**
  – Makes queue of tasks and executes one at a time

• **ExecutorService (subclass) constructors**
  – Lets you build FIFO, LIFO, and priority queues
Stopping a Thread

```java
public class SomeTask implements Runnable {
    private volatile boolean running;

    public void run(){
        running = true;
        while (running) {
            ...
        }
        doCleanup();
    }

    public void setRunning(boolean running) {
        this.running = running;
    }
}
```

Compilers on multiprocessor systems often do optimizations that prevent changes to variables from one thread from being seen by another thread. To guarantee that other threads see your changes, either use synchronized methods, declare the variable "volatile", or use AtomicBoolean.

Nasty Synchronization Bug (Part 1)

```java
public class Driver {
    public void startThreads() {
        ...
        for(…) {
            taskList.execute(new SomeHandler(...));
        }
    }
}
```

Separate class or inner class. But this problem does not happen when you put "this" here.
Nasty Synchronization Bug (Part 2)

```java
public class SomeHandler implements Runnable {
    public synchronized void doSomeOperation() {
        accessSomeSharedObject();
    }
    ...
    public void run() {
        while(someCondition) {
            doSomeOperation();   // Accesses shared data
            doSomeOtherOperation();  // No shared data
        }
    }
}
```

This keyword has no effect whatsoever in this context! Why?

Synchronization Solution

- **Solution 1: synchronize on outer class**
  - If your handler is an inner class, not a separate class

```java
public OuterClassName {
    public void someMethod() {
        ...
        taskList.execute(new SomeHandler(...));
    }
}

private class SomeHandler implements Runnable {
    public void run() { ...

    public void doSomeOperation() {
        synchronized(OuterClassName.this) {
            accessSomeSharedObject();
        }
    }
}
```
Synchronization Solutions

• Solution 2: synchronize on the shared data
  
  public void doSomeOperation() {
    synchronized(someSharedObject) {
      accessSomeSharedObject();
    }
  }

• Solution 3: synchronize on the class object
  
  public void doSomeOperation() {
    synchronized(SomeHandler.class) {
      accessSomeSharedObject();
    }
  }

  • Note that if you use “synchronized” for a static method, the lock is the corresponding Class object, not “this”.

Synchronization Solution (Continued)

• Solution 4: synchronize on arbitrary object
  
  public class SomeHandler implements Runnable{
    private static Object lockObject = new Object();
    ...
    public void doSomeOperation() {
      synchronized(lockObject) {
        accessSomeSharedObject();
      }
    }
    ...
  }

  – Why doesn’t this problem usually occur with thread mechanism two (with run method in main class)?
Determining Maximum Thread Pool Size

• In most apps, a reasonable guess is fine

```java
int maxThreads = 100;
ExecutorService taskList =
    Executors.newFixedThreadPool(maxThreads);
```

• If you need more precise values

```
maxThreads = numCpus * targetUtilization * 
    (1 + avgWaitTime/avgComputeTime)
```

  • Compute numCpus with
    Runtime.getRuntime().availableProcessors()
  • targetUtilization is from 0.0 to 1.0
  • Find ratio of wait to compute time with profiling
  • Equation taken from *Java Concurrency in Practice*
Other Advanced Topics

- **wait/waitForAll**
  - Releases the lock for other threads and suspends itself (placed in a queue associated with the lock)
  - Very important in some applications, but very hard to get right.

- **notify/notifyAll**
  - Wakes up all threads waiting for the lock
  - A notified thread doesn’t begin immediate execution, but is placed in the runnable thread queue

- **Concurrency utilities in java.util.concurrency**
  - Advanced threading utilities including semaphores, collections designed for multithreaded applications, atomic operations, etc.

- **Debugging thread problems**
  - Use JConsole

Summary

• Basic approach
  ExecutorService taskList =
    Executors.newFixedThreadPool(poolSize);

• Three variations
  – taskList.execute(new SeparateClass(…));
  – taskList.execute(this);
  – taskList.execute(new InnerClass(…));

• Handling shared data
  synchronized(referenceSharedByThreads) {
    getSharedData();
    modifySharedData();
  }
  doOtherStuff();

Really four variations, with lambdas being the fourth. But lambda expressions are not covered in detail yet.
